

SUBJECT: BIOCHEMISTRY

II SEMESTER B.PHARM (1st YEAR)

PRACTICAL LAB MANUAL

INTRODUCTION

GENERAL INSTRUCTIONS:

- Wear only cotton dress while working in the laboratory.
- Wear a white overcoat in the practical class.
- Maintain an observation book and bring it to every practical class.
- Do your practical work with concentration and avoid distractions and talking to your neighbours.
- Use reagents in prescribed amounts.
- Keep the reagents bottle in their places and do not interchange the stoppers, pipettes and droppers.
- Do not carry the common reagent to your table.
- Handle glassware carefully.
- While handling concentrated acids and alkalis, exercise caution and avoid mouth pipetting.
- No chemicals should be touched by fingers. Use the intended spatulas.
- Follow the first aid instructions when needed.
- While pipetting any solutions take care so that the tip of pipette is well inside the solution.
- Don't run the gas burner unnecessarily. Put them off when not required.
- Do every practical with theoretical knowledge and significance.
- Give your own observation for every test and inference according to your observation book.
- Every practical class is important. If you miss any class, do the relevant experiment during your leisure hours with permission from your teachers.
- Record the work done in the practical class neatly in the practical record book. Your record of work is assessed for internal marking. Brink your record note book after recording the previous experiment to every class.

FIRST AID EQUIPMENTS:

- First aid equipment is to be kept in the laboratory. The kit should contain the following in your box located in a central place. These should not be kept in a locked cupboard.
- 5% aqueous NaCO₃
- 2% aqueous NaHCO₃ in a dropper bottle

- 5% acetic acid
- Saturated solution of boric acid in a dropper bottle
- Glycerine tincture of iodine, Grease or Vaseline, Dettol, absorbent cotton, gauge, roller bandages, adhesive tape, scissors.

ACCIDENTS IN LABARATORY:

It may be caused by

1. Acid:

Splashes on the skin, splashes in the eye, swallowing while pipetting.

- 2. Alkalis
- 3. Toxic substances
- 4. Heat
 - Open flames
 - Hot liquids
 - · Inflammable liquids
 - Explosions
- 5. Broken glass
- 6. Contamination by infected material
- 7. Electric shock
- LABARATORY FIRST AID:
 - Inhalation injury is best treated by removal to the uncontaminated and ventilated area. Irritation of the throat is removed by warm, soothing drinks.
 - Chemical injuries to the eye by splashing require immediate attention by dilution of the affected area with plenty of water.
 - Chemical injuries to the mouth by entry of strong chemicals (acids or alkalis) while pipetting needs immediate dilution with water and washing the mouth.
 - Burn on the skin cools the area by ointment. Do not rub.
 - In all the above cases after first aid treatments ask for prompt medical attention from casualty department.

INTRODUCTION TO CARBOHYDRATE

DEFINITION:

Carbohydrates are defined as poly hydroxy alcohols with aldehyde or ketone and their derivatives. Carbon, hydrogen and oxygen are the elements which will compose the carbohydrate.

CLASSIFICATION:

Carbohydrates are divided into four major groups as follows,

Monosaccharide Disaccharides Oligosaccharides Polysaccharides

MONOS ACCHARIDE:

- They are simple sugars which cannot be hydrolysed by simple forms.
- They are represented by a general formula $C_n(H_2O)_n$
- Depending upon the carbon atoms they possess as trioses, tetroses, pentoses, hexoses, heptoses.
- If the aldehyde (CHO) is present in the structure that is aldoses
- If the ketone (-CO) group is present that is ketoses.

GENERAL FORMULA	ALDOSES	KETOSES
Trioses	Glyceraldehyde	Dihydroxy acetone
C ₃ H ₆ O ₃	Glyceroses	80 80
Tetroses	Erythrose	Erythrulose
C ₄ H ₆ O ₄		
Pentoses	Ribose, xylose, Arabinose	Ribulose, Xylulose, Arabilose
$C_5H_{10}O_5$		
Hexoses	Glucose	Fructose, Ketoses
$C_6H_{12}O_6$		****

Simplest form of aldoses
Simplest form of ketoses
-Glyceraldehyde
-Dihydroxy acetone

Commonest aldoses - Glucose
Commonest ketone - Fructose

Natural glucose $-\alpha$ –D glucose

DISACCHARIDES:

These sugars yields two molecules of same or different molecule of monosaccharide on hydrolysis. They are represented by a general formula $C_n(H_2O)_{n-1}$

Maltose (Hydrolysis) → 2 molecules of glucose

Lactose (Hydrolysis) → glucose + galactose

Sucrose (Hydrolysis) → glucose + fructose

OLIGOSACCHARIDES:

- These carbohydrates yield 3 to 10 monosaccharide units on hydrolysis.
- The oligosaccharides are of plant orgin

Raffinose (Hydrolysis) → fructose+ Galactose + glucose

(Trisaccharides)

Stachyose (Hydrolysis) → 2 molecules of Galactose + glucose+ fructose

(Tetrasaccharides)

Verbascose (Hydrolysis) → 3 molecules of Galactose + glucose+ fructose

(Pentasaccharides)

POLYSACCHARIDES: (Glycons)

These carbohydrates yield more than 10 molecules of monosaccharide on hydrolysis. They have higher molecular weight. They are mostly insoluble in water and tasteless

General formula: (C₆H₁₀O₅) n

Polysaccharides are two types

[A] HOMOPOLYSACCHARIDES: [HOMO GLYCONS]

These are the polymer of same monosaccharide units. Eg. Starch, glycogen, inulin, cellulose, dextrin, dextran

[B] HETROPOLYSACCHARIDES: [HETRO GLYCONS]

These are the polymer of different monosaccharide units or their derivatives.

Eg. Mucopolysaccharides (glucose amino glycons)

Hyaluronic acid

Chondroitin sulphate

Heparin

Keratan sulphate

BUFFER SOLUTION

INTRODUCTION:

A buffer solution is one that resists P^H change on the addition of acid or alkali. Such solution are used in many biochemical experiments where the P^H needg to be accurately controlled. From the Henderson – Hasselbalmh equation, the P^H of a buffer solution depend on two factorg; one is the pKa value and the other the ratio of salt to acid. This ratio is considered to be the same as the amount of salt and acid mixed together over the P^H range 4-10, where the concentration of hydrogen and hydroxyl ions is very low and can be ignored. Let us take the example acetate buffers consisting of a mixture of acetic acid and sodium acetate.

$$CH_3COOH \longleftrightarrow CH_3COO^- + H^+$$

$$CH_3COONa \rightarrow CH_3COO^- + Na^+$$

Since acetic acid is only weakly dissociated, the concentration of acetic acid is almost the same as the amount put in the mixture; likewise the concentration of acetate ion man be considered to be the same as the concentration of sodium acetate placed in the mixture since the salt is completely dissociated.

DEFINITION OF PH:

PH is defined as the negative logarithm of the hydrogen ion concentration.

MEASUREMENT OF PH:

The most convenient and reliable method for measuring P^H is by the use of a P^H meter which measures the e.m.f of a concentration cell formed from a reference electrode, the test solution, and a glass electrode sensitive to hydrogen ions.

GLASS ELECTRODE:

The glass electrode consists of a very thin bulb about 0.1 mm thick blown on to a hard glass tube of high resistance. Inside the bulb is a solution of hydrochloric acid (0.1 col/ litre)

connected to a platinum wire via a silver-silver chloride electrode, which is reversible to hydrogen ions. A potential is developed across the thin glass of the bulb which depends on the \mathbf{P}^{H} of the solution in which it is immersed. This potential is not readily affected by salts, protein or oxidizing and reducing agents, so the electrode can be used in a wide variety of media.

The glass electrode in the test solution constitutes a half cell and the measuring circuit is completed by a reference electrode which is not sensitive to hydrogen ions.

CALOMEL ELECTRODE:

The reference electrode commonly used is the calomel electrode similar to that illustrated. The calomel electrode is stable, easily prepared and the potential with respect to the standard hydrogen electrode is accurately known.

DATE:

PREPARATION OF CARBONATE BUFFER AND ITS MEASUREMENT

OF PH

AIM: To prepare carbonate buffer and it measurement of P^H by using P^H mete.r

MATERIALS REQUIRED:

- Sodium bicarbonate
- Sodium carbonate
- Distilled water
- ❖ 100ml volumetric flask
- Beaker
- Stirrer.

PROCEDURE:

To 93 ml of 0.1M sodium bicarbonate in volumetric flask and 0.1M sodium bicarbonate was added to make up the volume up to 100ml. The P^H was measured by the P^H meter.

Preparation of 0.1M sodium bicarbonate

8.4gm of sodium bicarbonate in 1000ml of water

Preparation of 0.1M sodium carbonate

28.6 g of sodium carbonate in 1000ml of water.

REPORT:

Carbonate buffer was prepared and the PH was found to be -----

DATE:

ISOLATION OF CASEIN FROM MILK

AIM: To isolate and identify the casein from given sample of milk.

MATERIALS REQUIRED:

- Beaker
- Glacial acetic acid
- Funnel
- Filter paper
- Milk.

PRINCIPLE:

Milk is the O/W type of emulsion. It contains proteins, carbohydrates, vitamins and minerals. The chief protein present in the milk is casein and β- albumin.

Casein is the phosphate protein containing about 0.85% phosphorous and 0.7% sulphur. It contains about 15 amino acids and it is rich in essential amino acids. Its isoelectric point is 4.6 and its nitrogen content is 15.16%. It's available in two forms,

ACID CASEIN:

Warm skimmed milk is acidified with dil .H2SO4RENNET

CASEIN:

Skimmed milk is treated with an enzymes when a rennet extract, glacial acetic acid is added with milk its isoelectric point brought to 4.6. Emulsion breaks and then the casein precipitate.

PROCEDURE:

100 ml of milk is warmed to 40°C in the beaker. Cooled and diluted with glacial acetic acid drop wise. The mixture is stirred well by agitation. Titration is done till the complete separation of the casein. It's removed by muslin cloth, dried in vacuum or open air till it forms amorphous mass. Remove it by knife and pressed with spatula to make powder form.

REPORT:

The casein was isolated from the milk.

EXP.NO. 3 DATE:

ESTIMATION OF URINARY CREATININE

AIM:

To estimate the amount of Creatinine present in the given urine sample

METHOD:

JAFFE'S METHOD

REAGENT:

Picric acid reagent -0.4M 0.75N Sodium hydroxide

PRINCIPLE:

Creatinine in urine reacts with picric acid in the presence of sodium hydroxide to give an red colour compound of creatinine picrate. The intensity of the colour is proportional to the amount of creatinine present and is compared with that of a standard creatinine solution similarly treated. The readings are taken in a colorimeter at 520 nm.

PROCEDURE:

Dilute urine solution (test solution): Dilute 1ml of urine to 100ml with distilled water in a standard flask. Take 3 test tubes and lable them as blank, standard, and test and proceed as follows

REAGENT (ml)	BLANK (ml)	STANDARD (ml)	TEST (ml)
Distilled water	5		
Working standard solution		5	
Sample solution			1
0.04M Pierie aeid	1	1	1
0.75N NaOH	1	1	1

Mix and allow to stands for 15 minutes. Measure the absorbance of standard, test and blank at 520nm.

NORMAL RANGE:

0.6-1.5mg/dl

REPORT:

The amount of Creatinine present in the given test solution was found to be -----mg/dl

CALCULATION:

Absorbance of test (T) = Absorbance of standard (s) = Absorbance of blank (B) = Urea concentration =

Absorbance of test- Absorbance of blank x Con. Of std x 100 Absorbance of std-Absorbance of blank Vol. of urine

Ex.No:4 GENERAL PROCEDURE FOR QUALITATIVE ANALYSIS OF CARBOHYDRATES

S.NO.	EXPERIMENT	OBSERVATION	INFERENCE	
1	Action of heat: Heat a small amount of substance in a dry test tube.	A black residue is formed	Presence carbohydrates	of
2	Action of conc.H ₂ SO ₄ Take a small amount of sample solution in a dry test tube and add 2ml of conc. H ₂ SO ₄	Solution becomes black in colour	Presence carbohydrates	of
3	Molisch's test: To 2 ml of given sample solution add 5 drops of Molisch's reagent. Then slowly add 2ml of conc. H ₂ SO ₄ along the sides of the test tube.	Violet ring is formed at the junction of two layers	Presence carbohydrates	of

Principle:

Carbohydrate when treated with conc. H₂SO₄ undergoes dehydration to give furfural derivatives. These furfural derivatives condense with phenols to form coloured products.

The phenol used in Molisch's reagent is α -naphthol. In case of oligo and polysaccharides they are first hydrolysed into monosaccharide by an acid, which undergoes dehydration to form furfural or its derivatives. Any carbohydrates with more than four carbon atoms will give positive test.

4	Benedict's test:			
	To 5ml of Benedict's reagent	An appearance of green,	Presence	of
	add 8drops of given sample. Boil	yellow, orange or brick red	reducing	sugars
	over a flame for 2 minutes or place	precipitate.	like	glucose,
	in a boiling water bath for three		fructose,	lactose
	minutes and allow to cool.		and malto	se.

Principle:

Benedict's reagent contains copper sulphate, sodium carbonate and sodium citrate.

Carbohydrates with free aldehyde or ketone groups have reducing properties.

The mild alkali sodium carbonate converts glucose into enediol. This enediol reduces copper sulphate to cuprous hydroxide that is unstable and decomposes on boiling to cuprous oxide. The precipitated cuprous oxide will have different shades of colour depending upon the concentration.

Sodium citrate present in this reagent prevents the precipitation of cupric ion as cupric hydroxide by forming cupric sodium citrate complex. It also improves the self life of the reagent by preventing an interaction between sodium carbonate and copper sulphate.

reagent by preventing an interaction between sodium carbonate and copper sulphate.

The at in the seliwanoff's characteristic form Presence of

The foulger's reagent is resorcinol in conc. sulphuric acid. The carbohydrates are converted into furfural derivatives by conc. sulphuric acid present in the foulger's reagent. Furfural derivatives of ketose sugar condense with resorcinol to form a blue colour compound.

10	Osazone test:		
	Take 10ml of sample solution	Sunflower like appearance	Presence c
	in a dry test tube add one spatula		maltose
	full of phenyl hydrazine and two	Dark yellow broomstick or	Presence c
	spatula full of sodium acetate and	needle like appearance	glucose an
	1ml of glacial acetic acid. Mix well	Training (1) to the colored at the second and the s	fructose.
	and filtered in a test tube. Filtrate is		
	kept in boiling water bath for 30	Powder puff or badminton	
	minutes. And examine the shape	ball shape	Presence of lactos
	of the crystal under the		
	microscope.		
	1		

Reducing sugar when treated with phenyl hydrazine in the presence of sodium acetate (PH - 5) give characteristic yellow coloured crystals of osazone.

Glucose and fructose give same type of osazone. Because they differ only at the first two carbon atoms which are masked by attachment of two molecules of phenyl hydrazine.

	CONFIRMATORY TEST FOR	SUCROSE		
11	Hydrolysis test: To 5ml of sample solution add 3 drops of conc. hydrochloric acid and boil for 1 minute. Cool and neutralize with 20% sodium carbonate solution till the effervescence ceases to the neutralized solution. Add 5ml of benedict's reagent and boil for 2 minutes and cool.		is	Presence of sucrose

Principle:

Sucrose does not reduce Benedict's reagent but hydrolysed and neutralized product of sucrose will answer for Benedict's reagent. This indicating the presence of reducing sugar in the hydrolysis of sucrose.

	CONFIRM	ATORY	TEST	FOR
POLYSA	CCHARIDES			
12	Iodine test: To the sample solution add few drops of N/50 iodine solution		rmed Pro	esence of starch

Principle:

The test depends upon the property of adsorption having the bigger polysaccharides molecules which adsorb the smaller iodine molecules and forms the blue coloured complex.

QUALITATIVE ANALYSIS OF UNKNOWN SAMPLE OF CARBOHYDRATES SAMPLE [III]

S.NO.	EXPERIMENT	OBSERVATION	INFERENCE
1	Action of heat: Heat a small amount of substance in a dry test tube.	A black residue is formed	Presence of carbohydrates
2	Action of cone.H ₂ SO ₄ Take a small amount of sample solution in a dry test tube and add 2ml of cone. H ₂ SO ₄	Solution becomes black in colour	Presence of carbohydrates
3	Molisch's test: To 2 ml of given sample solution add 5 drops of Molisch's reagent. Then slowly add 2ml of conc. H ₂ SO ₄ along the sides of the test tube.	Violet ring is formed at the junction of two layers	Presence of carbohydrates
4	Benedict's test: To 5ml of Benedict's reagent, add 8drops of given sample. Boil over a flame for 2 minutes or place in a boiling water bath for three minutes and allow to cool.	An appearance of green, yellow, orange or brick red precipitate.	Presence of reducing sugars like glucose, fructose, lactose and maltose.
5	Fehling's test: To the given sample solution add Fehling's A & B solution. Boil for 15 minutes on the water bath.	Brick red colour precipitate is formed	Presence of reducing sugars
6	Tollen's Mirror test: To 2ml o tollen's reagent add 2ml of sugar solution, mix well and boil for 2 minutes	Silver mirror is formed	Presence of reducing sugars

7	Barfoed's test: To 2ml of Barfoed's reagen,t add 1ml of sample solution and heat in boiling water bath for 2 minutes (or) boil directly for 30 seconds & then Cool	Presence of disaccharides
8	Osazone test: Take 10ml of sample solution in a dry test tube. Add one spatula full of phenyl hydrazine and two spatulas full of sodium acetate and 1ml of glacial acetic acid. Mix well and filtered in a test tube. Filtrate is kept in boiling water bath for 30 minutes. And examine the shape of the crystal under the microscope.	Presence of lactose.

INTRODUCTION: REACTION OF PROTEIN

Proteins are high molecular weight mixed polymers of α -amino acids joined together with peptide linkage.

Proteins are macromolecules and they form colloidal systems. Most of them are hydrophilic, therefore, they are hydrated. Being colloids, they are charged. Hence proteins can be precipitated by dehydration and neutralization of the electrical charges, which they carry, to bring them to the isoelectric point P^H.

All Proteins do not contain the same amino acids. The various amino acid constituents of proteins may be identified by various colour reactions. Based upon physical and chemical properties and the presence of different amino acids, proteins in a given solution can be analyzed under the following headings,

- *Precipitation of protein
- * Colour reaction of protein
- * Reaction of specific protein

Eg. Albumin, globulin, Metaprotein, proteoses and peptones, Casein, mucin and gelatin

PRECIPITATION OF PROTEIN:

S.NO.	EXPERIMENT	OBSERVATION	INFERENCE
1.	PRECIPITATION BY		
	SOLUTION OF HEAVY		
	METALS:		
	• Take 3ml of protein	White precipitate is	Presence of protein
	solution and add 5%	obtained	(908)
	mercuric nitrate or		
	mercuric sulphate drop		
	by drop and observe	White precipitate is	Presence of protein
	the precipitate.	obtained	
	Take 3ml of protein		
	solution and add 10%		
	lead acetate solution		
	drop by drop and		
. 4	observe the precipitate.		

PRINCIPLE:

Proteins exist as negatively charged ions(anions) in pH higher than their isoelectric pH. To such a solution if salt of heavy metals are added, positively charged metal ions can complex with protein anion and metal proteinates are formed which gets precipitated.

2.	PRECIPITATION BY ALKALOIDS REAGENT: To 2ml of protein solution, add 2 drops of 20% sulphosalicylic acid.	White precipitate or turbidity appears.	Protein is precipitated by sulpho salicylic acid.
	roteins exist as positively charge alkaloidal reagents have negati		lower than their isoelectric PH. positive charges thus resulting in
3.	PRECIPITATION BY ALCOHOLS: Take a 2ml of protein solution add 2ml of alcohol.	White precipitate is formed.	Presence of protein
PRINC Pred protein 4.	cipitation occurs by alcohol due to	dehydration or denat	uration and removal of charges of
	NEUTRAL SALT: HALF SATURATION: Take 3ml of protein solution in a test tube; add an equal volume of saturated ammonium sulphate solution to it, mixed and allowed to stand.	White precipitate is formed. White precipitate is	Presence of protein Presence of protein
	FULL SATURATION: Take 3ml of protein solution, add ammonium sulphate salt to it and keep on adding and at the same time mix till protein solution become saturated.	formed.	

PRINCIPLE:

Neutral salts like ammonium sulphate precipitate protein by neutralization of charges on the protein and dehydration.

5.	PRECIPITATION BY		
	ACIDS:	White precipitate is	Protein is precipitate by nitric
	Take 3ml of conc. nitric acid	formed at the	acid.
	in a test tube; slowly add	junction of two	
	protein solution along the	layers.	
	sides of the test tube.	5529	

PRINCIPLE:

Conc. Acid causes denaturation of protein, which brings native proteins into insoluble acid metaprotein. Derived proteins like gelatin and peptone are not sufficiently denaturated by acids and thus do not get precipitated.

40			
6.	PRECIPITATION BY ALKALIES: To 3ml of protein solutions, add 2ml of 40% sodium hydroxide and observe.	* *	Presence of gelatin and casein. Presence of albumin and peptones.
	PRINCIPLE: Casein and gelatin get der soluble, hence not precipitated.	natured by alkali but	alkali metaprotein of albumin is
7.	PRECIPITATION AT ISOELECTRIC pH To 3ml of casein solution add a drop of bromocresol green (BCG) solution. Note the colour; add 2% acetic acid drop by drop till colour changes to green.	casein. Bromocresol green has a green colour	Presence of casein

PRINCIPLE:

The solubility of protein is minimum at their isoelectric pH as the protein molecules become electrically neutral at this pH.

casein

DATE:

COLOUR REACTIONS OF PROTEINS AND AMINO ACIDS:

INTRODUCTION:

Proteins are polymers of amino acids and are macromolecules. Principal linkage in proteins is peptide bond which binds the various amino acids in it. Proteins give characteristic colour on treatment with certain reagents due to presence of different amino acids or a class of amino acids having a characteristic group or due to certain grouping in the protein molecules.

S.NO.	EXPERIMENTS	OBSERVATION	INFERENCE	
1.	BIURET TEST:	Purple or pinkish	Presence of peptide bond of	
	To 3ml of protein solution	purple is produced.	protein.	
	add an equal volume of 5%			
	NaOH and 3 to 4 drops of 1%			
	copper sulphate.			
	PRINCIPLE:			
	This test is positive for all co	ompounds containing	more than one peptide linkage	
	Since all proteins contain peptide linkages, they respond to this test. The purple o			
			ination complex between cupri-	
	hydroxide and the peptide bond. The colour intensity depends upon the presence o number of peptide linkages.			
2.	XANTHOPROTEIC TEST:	There is depending	Presence of aromatic amino	
	To 3ml of protein solution	of yellow colour	acid.	
	add 1ml cone.nitric acid boil			
	for about half a minute. Cool			
	and observe yellow colour.

	TRYPTOPHAN)	Violet ring is	Presence of tryptophan in
	To 3ml of protein solution	formed at the	protein.
	add 2 drops of 1 in 500	junction of the	
	formalin and 1 drop of 10%	layer	
	mercuric sulphate (prepared in		
	10% sulphuric acid). Mix well		
	then added gently through the		
	side of the test tube about 3ml		
	cone. Sulphuric acid.		
	PRINCIPLE:		
	Aldehyde (aldehyde) react	ts with the oxidized 1	product of the indole nucleus of
	tryptophan to give violet colou	red complex (sulphur	ic acid with mercuric sulphate is
	used as oxidizing agent in this re	eaction).	
	0000	9809	
5.	SAKAGUCHIS' TEST:	A caramine red	Presence of arginine
	To 5ml of protein	colour developed.	
	solution add 5 drops of 5 %		
	sodium hydroxide and 4 drops		
	molichs' reagent. Mix and add		
	10 drops of bromine water.		
	PRINCIPLE:		
	AND ENGINE AND ADDRESS.	othol combine with th	e guanidine group of arginine to
1			uce a caramine red colour.

6.	SULPHUR TEST: To 3ml of protein solution add an equal volume of 40% sodium hydroxide and boil for 3 minutes. Cool and then add 1ml of lead acetate solution.	A dark grey or black precipitate is obtained.	Presence of sulphur containing aminoacid cysteine and cystine. Methionine does not answer to this test due to presence of thioether linkage which does not allow the release of sulphur in this reaction.	
	PRINCIPLE: When cysteine and cystine are boiled with strong alkali, organic sulphur is converted to sulphide (Na ₂ S). This sodium sulphide react with lead acetate to form a black grey precipitate of lead sulphide			
7.	NINHYDRIN TEST: To 3ml protein solution add 3 drops of ninhydrin reagent in the (0.1% in acetone) heated to boil and cool.	colour is obtained. Yellow colour is	Presence of α-amino acid. Presence of proline and hydroxyl proline.	
	PRINCIPLE: Ninhydrin react with free α-amino acid to give bluish purple colour. Ninhydrin is a powerful oxidizing agent and causes oxidative decarboxylation of alpha amino acid producing an aldehyde. The reduced ninhydrin then react with ammonia and another molecule of ninhydrin and produces a bluish purple colour compound.			
8.	MOLISCH'S TEST: To 2ml of protein solutions add 6 drops of 1% molisch's reagent, add 2ml conc. Sulphuric acid along the side of the test tube.	Violet ring is formed at the junction of the solutions.	Presence of glycoprotein	

PRINCIPLE:

Carbohydrates present in protein when treated with conc. H₂SO₄ undergo dehydration to give furfural derivatives. These furfural derivatives condense with phenols to form coloured products.

The phenol used in Molisch's reagent is α -naphthol. In case of oligo and polysaccharides they are first hydrolysed into monosaccharide by acids, which undergoes dehydration to form furfural or its derivatives. Any carbohydrates with more than four carbon atoms will give positive test.

QUALITATIVE ANALYSIS OF LIPIDS

INTRODUCTION:

Lipids are insoluble in water but soluble in solvents like alcohol, ether, chloroform etc. The lipids in the human body consist of neutral fats, phospholipids, cerebrosides, cholesterol and cholesterol esters, free fatty acids.

Lipids are transported in blood as lipoprotein, after combination with the apoproteins in the liver and to some extent in the small intestines. The different lipids carried by lipoproteins include triacylglycerols, phospholipids, cholesterol and its esters and free fatty acids. As lipids are hydrophobic they are necessarily converted into hydrophilic lipoprotein for transport in the aqueous medium of blood.

GENERAL PROCEDURE FOR QUALITATIVE ANALYSIS OF LIPIDS

S.NO	EXPERIMENTS	OBSERVATION	INFERENCE
1.	FILTER PAPER TEST:	Transparent spot	Presence of lipids
	Place a drop of given sample in its	occurs	***
	filter paper and allow to dry and		
	observe after 5 minutes		
2.	GREASE –SPOT TEST:	A translucent spot	Presence of fat
	Put a drop of oil over a piece of	occurs	
	ordinary writing paper		
	PRINCIPLE:		
45	All the lipids are greasy in nature		
3.	SOLUBILITY TEST:	In water oil is	Presence of lipids
	Take 2 dry test tubes and add 2ml of	broken into small	
	water, ether, to test tube 1, 2,	droplets and floats	
	respectively, now add 1 drop of oil to	on the surface.	
	each test tube and shake well.	But in other	
	PRINCIPLE:	solvents oil is	
	Oil is insoluble in polar solvents	disappears	
	(water) but soluble in non polar		
	solvents (ether, ethyl alcohol,		
	chloroform and benzene)		

4.	EMULSIFICATION TEST: To 2ml of water in a test tube add one drop of oil and shake vigorously. Allow the test tube to stand and observe. PRINCIPLE: When oil and water which are immininto very tiny droplets which are dispension.		gether the oil is broken up
5.	SAPONIFICATION TEST: To the ten drops of given oil 20 drops of 40% potassium hydroxide or 20% sodium hydroxide are mixed in a test tube and kept in a boiling water bath for 10 minutes till the solution is clear. Cool this mixture and divide into 4 parts • Two test tubes are taken, in one test tube take 5ml of water and other test tube take chloroform and add 3 drops of given sample solution in each test tube. • To 2ml of sample solution add 3 drops of conc. HCl. • To 2ml of sample solution add 2% calcium chloride • Add 2ml of sample solution to 2ml of saturated sodium chloride	Dissolve in water and precipitate in chloroform Fatty acids separate out White precipitate is formed. Precipitate is formed	Fats when treated with alkali hydroxide liberate fatty acids. This reaction of alkaline to form salt is called soaps. Soaps are insoluble in chloroform, but soluble in water. Conc. Acid cause hydrolysis of soap Precipitate by calcium salts is called saponification. Precipitate by sodium salts is called saponification.
6.	TEST FOR UNSATURATION: • Take 1ml of given oil, dissolve in 1ml of alcohol and2 drops of bromine water.	Decolourisation of bromine water takes place. No decolourisation of bromine water takes place	Presence of unsaturated fat. Presence of saturated fat.

	 To 2ml of solution add 2% calcium chloride Add 2ml of sample solution to 2ml of saturated sodium chloride 	Precipitate is formed	Precipitate by calcium salts called saponification.
			Precipitate by sodium salts called saponification.
6.	 TEST FOR UNSATURATION: Take 1ml of given oil, dissolve in 1ml of alcohol 2 drops of bromine water. 	Decolourisation of bromine water takes place.	Presence of unsaturated fat.
	 Take 1ml of given oil, dissolve in 1ml of alcohol 2 drops of KMno₄ water. 	Decolourisation is occurs	Presence of unsaturated fat.
7.	TEST FOR STEROIDS: • SALKOWSKI'S TEST: Take 5ml of sample in chloroform in a dry test tube; add gently along the sides, an equal volume of conc. sulphuric acid. Observe the upper chloroform layer and the lower acid layer.	The acid layer develops a yellow colour with green fluorescence. The chloroform layer will give a relay of colour from bluish red to gradually violet colour.	Presence of cholesterol

LIEBERMANN- BURCHARD
 REACTION:
 To about 2ml of sample dissolve in chloroform in a dry test tube and add 2ml of acetic anhydride and 2-3 drops of conc. Sulphuric acid. Mix and stand for a few minutes in the dark.

An emerald green colour develops.

Presence of cholesterol

REPORT:

The given sample contain

- (i). Lipids
- (ii). Unsaturated lipids
- (iii). Cholesterol

DATE:

GENERAL PROCEDURE FOR ANALYSIS OF NORMAL CONSTITUENT OF URINE

S.NO.	EXPERIMENT	OBSERVATION	INFERENCE
	Physical Examination:		
1.	a) Appearance b)Colour c)PH	Clear	Normal urine is clear and transparent. Due to the presence of
	d)Specific gravity	Straw coloured 6 1.018	urochrome. PH of the normal urine is 4.8-7.0
			Normal specific gravity of urine is
			1.016-1.022
2.	Test for inorganic constituent: a) Test for chloride:		
	To the 5ml of urine sample, add con. nitric acid and 1ml of 3% silver nitrate.	A white precipitate of silver chloride is formed.	Presence of chloride in urine
	b)Test for calcium and Phosphates: Take 10ml of urine add 2ml		
	of ammonium hydroxide boil it & cool, then filter it. Filtrate is	White precipitate is formed.	

r			
	collected and the precipitate is dissolved in quantity of acetic acid and divided into 2 parts. i) To one part, add 1ml of 5% potassium oxalate solution. Ii) To the 2 nd part, add 1ml con. nitric acid if necessary boil and add 1ml of	Yellow colour precipitate	Presence of calcium.
	ammonium molybdate reagent and mix well. c) Test for ammonia:	occurs.	Presence of phosphate.
	Take 5ml of urine in a test tube & add a drop of phenolphthalein and add 2% sodium carbonate drop by drop	Dhanalahtha laika in dia d	Draganae of annual
	until the colour becomes faint pink. Allow to boil and hold a glass rod dipped in phenolphthalein at the mouth of the test tube. d) Test for inorganic sulphate:	Phenolphthalein indicator in the glass rod changes to pink colour.	Presence of ammonia.
	Take 5ml of urine in a test tube. Add 1ml of con. Hydrochloric acid. Mix well and add 5ml of 10% bariumchloride solution. Filter it and use the filtrate for next experiment.	to the same of the same	Presence of inorganic sulphate.
3.	Test for organic constituent: Collect the above filtrate & allow it to boil.	Precipitate is formed.	Due to the presence of organic constituent.
4.	Test for urea: Take 5ml of urine in a test tube & add 2 drops of freshly prepared alkaline sodium hypobromite solution.	Effervescence is produced.	Alkaline hypobromite react with urea which forms gases like nitrogen & co ₂
<u> </u>		<u>.</u>	

5.	Test for creatinine: Jaffe's test: 3ml of urine and 3ml of water are taken in 2 separate test		
	tubes. 1ml of saturated picric acid and 10 drops of 10% sodium hydroxide are added to both the test tubes and mixed. Wait for 5 minutes.	Orange red colour is developed in the test tube containing urine.	Due to the formation of creatinine picrate
6.	Test for uric acid: Take 3ml of urine and add 1ml of 1% sodium carbonate and 1ml of dil. Phosphotungstic acid.	Blue colour is appeared.	Presence of uric acid.

The constituents of normal urine are

- Chloride
- Calcium
- Phosphate
- Ammonia
- Inorganic sulphate
- Organic constituent
- Urea
- Creatinine
- Uric acid

GENERAL PROCEDURE FOR ANALYSIS OF ABNORMAL CONSTITUENT OF URINE

(Pathological constituents of urine)

The commonly encountered pathological chemical constituents of urine are

- 1. PROTEIN: May be albumin or globulin
- 2. BLOOD: Haemoglobin, Erythrocytes
- 3. REDUCING SUGAR: Usually glucose and in special cases lactose, galactose, pentose and rarely fructose
 - 4. KETONE BODIES: Acetone, aceto acetic acid
- 5. BILE SALTS & BILE PIGMENTS: Sodium and potassium salts of glycol/taurcholic acids, Bilirubin
 - 6. PORPHOBILINOGEN

7. UROBILINOGEN

S.NO.	EXPERIMENT	OBSERVATION	INFERENCE
1.	TEST FOR PROTEIN:		Presence of protein
	a)Heat coagulation test:	Coagulation occurs	
	Fill ³ / ₄ of a test tube with the urine acidified with 2% acetic acid mix & heat the upper portion.		
	Principle: Urine contains mainly all	oumin which is a heat coag	ulable protein
	b) Sulphosalicylic acid test: To 5ml of urine, add 1ml of 20% Sulpho salicylic acid.	White precipitate is formed	Presence of protein
	Principle: Protein is precipitated by protein	Sulpho salicylic acid by r	emoval of charges on the
	c)Heller's test: Take 3ml of con. Nitric acid and add 2ml of urine along the sides of test tube.	A white ring of meta proteins appears at the junction of the fluids.	Presence of protein in the urine sample.

2.	TEST FOR BLOOD:		
	a)Ortho-Tolidine test:		Presence of
	To 6 drops of freshly prepared O-Tolidine add 6 drops of hydrogen peroxide and 4 drops of previously boiled urine.	A transient dark green colour is formed	haemoglobin
	Principle:		
	Heme part of haemoglobin has oxygen from H ₂ O ₂ . This nascent ox Colour disappears after few minutes	ygen oxidizes O-Tolidine	
	b)Benzidine test:		
	To 6 drops of freshly prepared		Presence of
	benzlidine add 6 drops of hydrogen peroxide and 4 drops of previously boiled urine.	A transient dark green colour is formed	haemoglobin
3.	TEST FOR REDUCING		
	SUGAR: Benedict's test:	Colour changes from blue to green, yellow,	Presence of reducing sugar.
	To 5ml of Benedict's reagent, add 8 drops of urine sample. Boil over a flame for 2 minutes or place in a boiling water bath for three minutes and allow to cool.	orange or brick red precipitate.	
	Principle:		
	Benedict's reagents contain citrate. The mild alkali sodium car reduces copper sulphate to cuprou boiling to cuprous oxide. The preci	bonate converts glucose in hydroxide that is unst	into enediol. This enediol able and decomposes on
4.	TEST FOR KETONE BODIES:		
	a)Rother's test:		
	Take 5ml of urine and fully saturated with solid ammonium sulphate. This is to remove substances, which may interfere with the test. Then, add5 drops of a freshly prepared solution of sodium nitro prusside and gently	A permanganate colour appears.	Presence of acetone
	shake. Then add a few ml of con.ammonia and mix it.		

ŢF			
	Principle:		
	The nitro prusside in alkaline	The state of the s	nonia) react with ketone
	group to form a permanganate color	ır.	
	b)Gerhardt's test:		Presence of aceto acetic
	To about 5ml urine in a test	A wine red colour	acid
	tube, add drop wise 10% ferric	appear	
	Chloride		
5.	TEST FOR BILE SALTS &		
	BILE PIGMENTS:		
	a)Hay's test: (for bile salt)		/
		Test tube (A)	Presence of bilesalts
	Take two test tubes one with	containing sulphur	
	5ml urine (A) and other with 5ml	powder sink.	
	of water (B). Now, gently sprinkle		
	flowers of sulphur into both.		
	Principle:		
	Add and 20th or Provided Charles (M. Europe Scholer)	41-41-11	<u> </u>
	Hay's test is based on the fac	t that blie saits lower the	surface tension of urine
	allowing the sulphur to sink.		
	b) Fouchet's test : (For bile		
	pigments) Take 5ml of urine add a few	Green colour appear	Presence of bile
	crystals of magnesium sulphate	Constitution 1	pigments
	and shake the tube till it		
	dissolves. Now add 10% barium		
	chloride in excess (about 10ml).		
	A precipitate of barium sulphate		
	is formed. The bile pigment get		
	adsorbed to the precipitate of		
	barium sulphate. Filter the		
	contents of the tubes, the filter		
	may be discarded. Dry the		
	precipitate by using filter paper.		
	To the dry precipitate add a drop		
	of fouchets reagent that contain		
	ferric chlorides as the oxidising		
	agent		
	Principle:		
	Ferric chloride reagent act as a	oxidizing agent it oxidis	es bilirubin to biliverdin
	(green) or bilicyanin (blue)		

6. TEST FOR UROBILINO AND PORPHOBILINOGI Ehrlich's diazo test: To 5ml of urine add 5ml	N: Chloroform layer changes to pink colour	of
ehrlichs diazo reagent mix and allow it to stand fo mts. Add 5ml of saturated so acetate and mix. Now add 5 chloroform and shake vigor for a few seconds and allow layers to separate.	10 lium al of usly Aqueous layer changes to pink colour Presence Porphobilingen	of
